MEASUREMENT Principle

UVFL Sulfur (SD-210 detector)

Sulfur Measurement

The sample is injected with argon carrier gas into the pyrolysis tube of high temperature (900 to 1000°C). Sulfur compounds in the sample are pyrolyzed and oxidized with O_2 gas.

$$R\text{-}S + O_2 \rightarrow SO_2 + SO_3 + \text{combustion product}$$

The produced SO_2 gas is excited (SO_2^*) by irradiating the ultraviolet ray $\nu 1$ (190-230nm). Then, SO_2^* emits the energy (fluorescent ultraviolet ray) and returns to the ground state.

$$SO_2 + h\nu 1 \rightarrow SO_2^* \rightarrow SO_2 + h\nu 2$$

This fluorescent ultraviolet ray $\nu 2$ (300-400nm) is received by the photomultiplier tube and AREA value is obtained. The sulfur concentration is obtained by calibration curve preliminarily drawn with the standard solution.

■SD-210 Detector

Chemiluminescence Nitrogen (ND-210 detector)

Nitrogen Measurement

Sample is injected into a high-temperature (900 to 1000°C) pyrolysis tube by argon carrier gas. After nitrogen compounds in the sample are pyrolyzed, it is combusted, oxidized, and converted to nitric oxide (NO). After removing moisture from the combustion gas by a dehumidifier (tube dryer), the following oxidation reaction occurs by reaction of NO with ozone.

$$NO + O_3 \rightarrow NO_2 + O_2 + h\nu$$

By this reaction, 590 to 2,500mm wavelength light is generated. The optical intensity of this light is proportional to the NO concentration at a wide frequency range. After emitted light is detected by a photomultiplier tube and signal processing is run, an area value is obtained. Using the relation between area and concentration (calibration curve) obtained from standard solutions, the total nitrogen concentration in the sample is calculated. Though some samples generate interfering substances such as SOx and CO in the process of decomposition to NO, there is little influence on measurement by chemiluminescence method by reduced pressure method.

Microcoulometry (MCD-210 detector)

Chlorine Analysis

Samples are combusted in an argon/oxygen atmosphere. The resulting hydrogen chloride is led into a titration cell where it is automatically titrated by silver ions generated coulometrically. The amount of chlorine is calculated from the quantity of electricity required for the titration.

$$HCl + Ag^+ \rightarrow H^+ + AgCl \text{ (titration)}$$
$$Ag \rightarrow Ag^+ + e^- \text{ (electrolysis)}$$

Sulfur Analysis

Samples are combusted in an argon/oxygen atmosphere. The resulting sulfur dioxide is led into a titration cell where it is automatically titrated by triiodide ions generated coulometrically. The amount of sulfur is calculated from the quantity of electricity required for the titration.

$$SO_2 + I_3^- + H_2O \rightarrow SO_3 + 3I^- + 2H^+ \text{ (titration)}$$
$$3I^- \rightarrow I_3^- + 2e^- \text{ (electrolysis)}$$

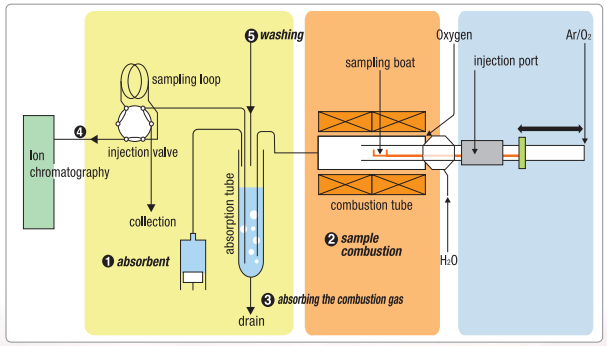
APPLICATION and OPTION

Prep-station for combustion-IC (Sulfur and Halides) analysis.

Measuring Principle

After samples are thermally digested in Argon atmosphere they are combusted with oxygen and H_2O. Sulfur in the samples changes to SO_x and Halogens turn to Hydrogen Halide and Halogen gas. These elements will be trapped by the absorbent solution, then injected for IC analysis.

Sample	In the combustion tube	In the absorbent	
Sulfur	SO_x	SO_4^{2-}	→ Ion Chromatograph
Halogen	HX, X_2	X^-	



Process Flowchart

2. pyrohydrolytic combustion of sample
3. combusted gas is absorbed by absorbent
4. absorbent is injected into the Ion chromatograph
